Complete fusion reactions: a brief overview

Nucleus-nucleus collisions at low and intermediate energies are the ideal playground to explore the evolution of reaction mechanisms with the collision energy and to probe the interplay of nuclear structure and dynamics (including the occurrence of collective motions in hot rotating nuclei).

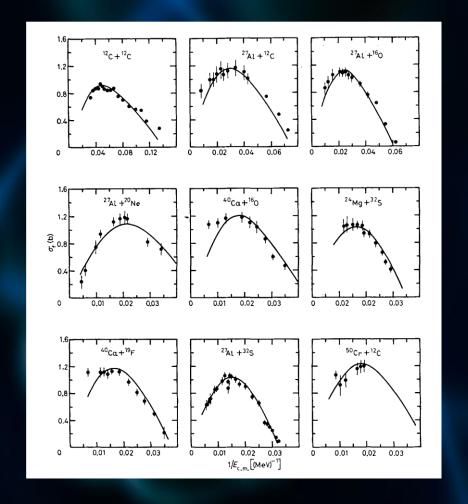

- Different, complementary, experimental methods can be effectively used to estimate the yield of evaporation residues (gamma-ray analysis, time-of-flight and magnetic spectrometers, charged particle detection with telescope arrays) → heavy-ion fusion cross section from the Coulomb barrier to the onset of multi-fragmentation \rightarrow
- See e.g. P. Frobrich, Phys. Rep. 116 (1984) 337.

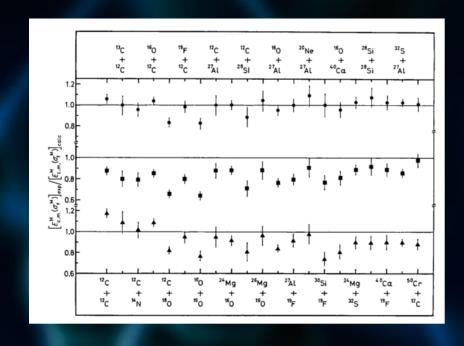

Models for the description of fusion cross section between heavy-ions:

- Microscopical approaches: Time-Dependent Hartree Fock (TDHF), Molecular dynamics;
- Macroscopic models: critical distance models, limitation to the compound nucleus model (empirical nuclear potentials from semi-classical considerations);
- Empirical models: starting from nuclear reaction theory and then optimizing to the experimental data.

Previous data-driven (phenomenological) approaches, see e.g. Porto F and Sambataro S **1984 Nuov. Cim. 83 339** → good description of data around the maxima of the cross section \rightarrow few datasets in Region III (high energies) and Region I (close to the Coulomb barrier).

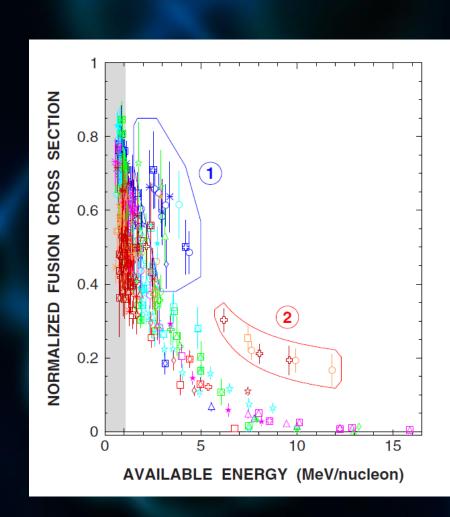

from P. Eudes et al., Phys. Rev. 90 (2014) 034609

Complete fusion reactions: a brief overview

More recently → systematic study of Region III shows discrepancies for some of the systems → further investigation on both experiment and theory is required!

Fusion cross section in Region III → disagreement with the prediction of state-of-the-art for some collision systems such as:

- ²⁸Si+¹²C
- 12C+27AI
- 48Ti+40Ca
- ¹⁶O+⁴⁰Ca
- 14N+12C
- ¹⁴N+¹⁴N
- 14N+27AI
- ¹⁴N+⁵²Cr
- ¹⁴N+⁵⁸Ni

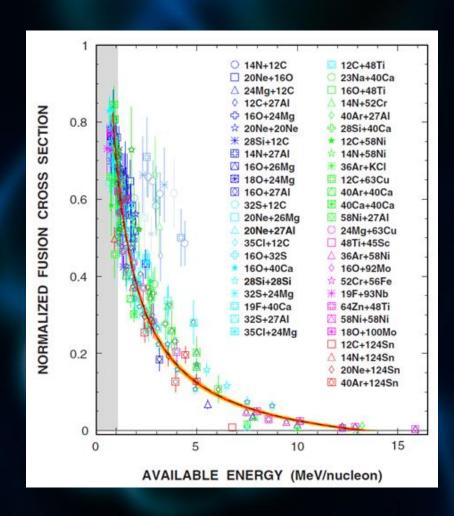

from P. Eudes et al., Phys. Rev. \mathcal{C} 90 (2014) 034609

Approach, dataset, and modeling

About 50 years of systematics (see e.g. Nuclear Reactions Video: Karpov A et al., 2017 Nucl. Instrum. Meth. Phys. Res. A 859 112; Zagrebaev V et al., 1999 NRV web knowledge base on low-energy nuclear physics URL http://nrwiim.ku/ for a complete database) → Possibility to derive new data-driven models for the description of the fusion cross section between heavy-ions in Regions I-III.

Approach, dataset, and modeling

Approach: supervised learning using symbolic regression algorithms.

Novelties:

- Deriving mathematical expressions to describe the data → support to theories and models attempting to predict the fusion cross section between heavy-ions;
- Comprehensive analysis of large amount of nuclear data → universal model for the description of the entire dataset;
- Advanced feature selection → allows to inspect the dependence on several variables (including nuclear structure variables).

Major challenges:

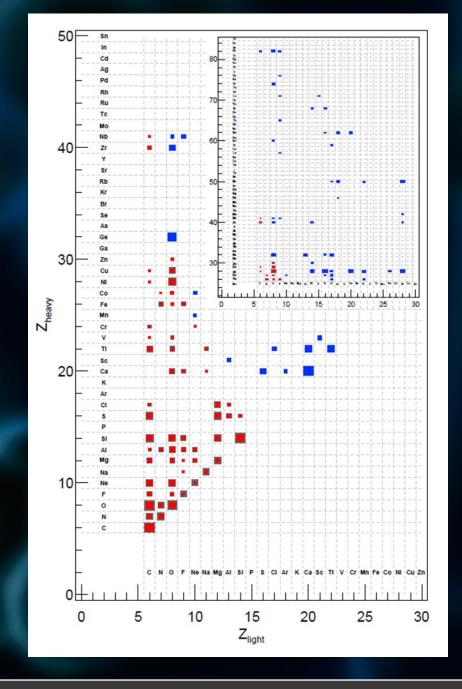

- The amplitude of the cross section varies even by several orders of magnitude with the energy;
- Experimental errors associated to each individual data point differ by several orders of magnitude for each data point;
- Resulting models must have physical boundaries and extrapolation capabilities.

We used an extensive set of nuclear features linked to:

- 1) The nature of the collision partners;
- 2) The energy of the collision;
- 3) The structure of the collision partners;
- 4) The structure of the compound nucleus.

Symbol	Description
E_{cm}	collision center-of-mass energy (MeV)
Z_1	charge of the first reaction partner
Z_2	charge of the second reaction partner
N_1	number of neutrons of the first reaction partner
N_2	number of neutrons of the second reaction partner
A_1	mass of the first reaction partner
A_2	mass of the second reaction partner
J_1	spin of the first reaction partner
J_2	spin of the second reaction partner
π_1	parity of the first reaction partner (1 for positive parity, -1 for negative parity)
π_2	parity of the second reaction partner (1 for positive parity, -1 for negative parity)
μ_1	magnetic dipole momentum of the first reaction partner (μ_N)
μ_2	magnetic dipole momentum of the second reaction partner (μ_N)
$\langle r^2 \rangle_1$	rms charge radius of the first reaction partner (fm)
$\langle r^2 \rangle_2$	rms charge radius of the second reaction partner (fm)
Q-value	fusion Q -value (MeV)
S_{α}	α separation energy of the compound nucleus (MeV)
S_n	one-neutron separation energy of the compound nucleus (MeV)
S_{2n}	two-neutron separation energy of the compound nucleus (MeV)
S_p	one-proton separation energy of the compound nucleus (MeV)
S_{2p}	two-proton separation energy of the compound nucleus (MeV)
$S_{\alpha 1}$	α separation energy of the first reaction partner
$S_{\alpha 2}$	α separation energy of the second reaction partner
S_{n1}	one-neutron separation energy of the first reaction partner
S_{n2}	one-neutron separation energy of the second reaction partner
S_{p1}	one-proton separation energy of the first reaction partner
S_{p_2}	one-proton separation energy of the second reaction partner
S_{2n1}	two-neutron separation energy of the first reaction partner
S_{2n2}	two-neutron separation energy of the second reaction partner
S_{2p_2}	two-proton separation energy of the first reaction partner
S_{2p2}	two-proton separation energy of the second reaction partner

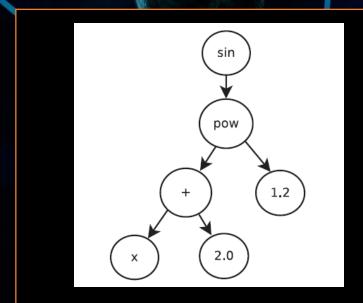

- Dataset used for model derivation → about 4500 experimental data points.
- Learning dataset: $Z_p Z_t < 250 \rightarrow$ light-to-medium mass nuclei.
- Testing dataset 1: $Z_p Z_t \ge 250 \rightarrow$ heavy systems (test the extrapolation towards heavy systems).
- Testing dataset 2: $Z_p Z_t < 250 \rightarrow$ some of the lighter systems.

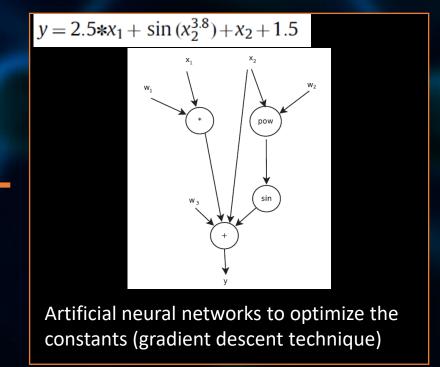

The Brain Project

Brain Project – a neural-genetic tool for the formal modeling of data

Exploits a novel hybridization of genetic programming and artificial neural network \rightarrow the task is that of symbolic regression. Genetic part \rightarrow foresees the evolution of tree-like structures representing mathematical expressions \rightarrow deals with the global search for the maximum of a suitable fitness function; Neural part \rightarrow deals with the local search for the minimum of the error when the genetic part has identified a good maximum of the fitness function.

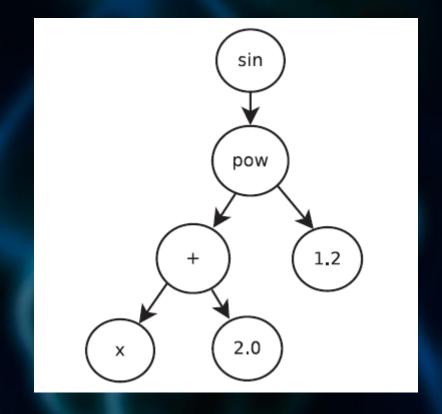

Genetic evolution of tree-like structures representing mathematical expressions

The Brain Project: genetic mechanism

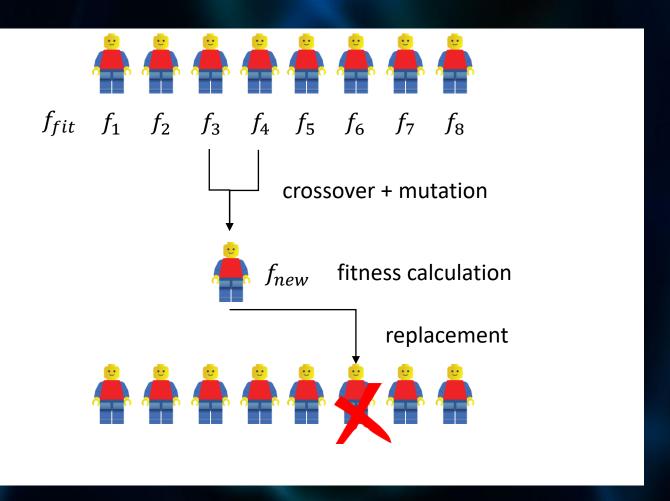

Brain Project: the genetic part forsees the evolution of tree-like structures representing mathematical expressions to model the data. In these structures, a node is a mathematical function or operation, a constant or a variable. The number of nodes is used to evaluate the complexity of the model.

→ See e.g. John R. Koza, Genetic Programming – On the Programming of Computers by Means of Natural Selection, A Bradford Book – The MIT Press (Cambridge, Massachussets; London, England)

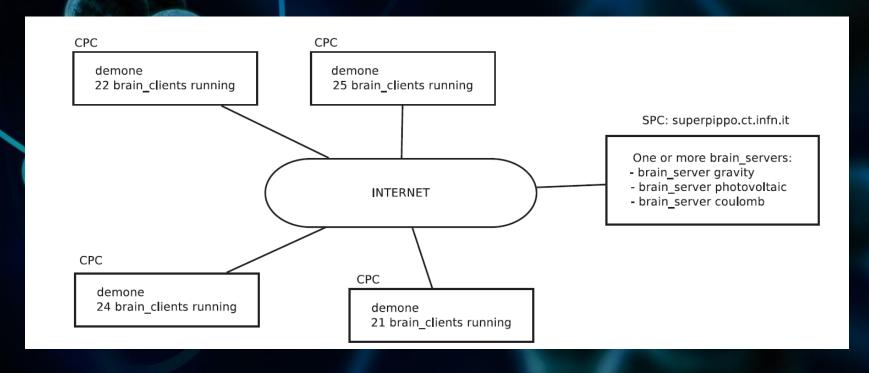

The Brain Project: genetic mechanism

- A set of possible solutions to the optimization problem, encoded according to a predefined scheme, is generated (often randomly). Each of such solutions is called *individual*. A set of individuals forms a *population*.
- 2. A numerical value, called *fitness*, is associated to each individual. The fitness quantifies how much a given solution is *suitable* to the problem to solve. Generally speaking, the higher is the fitness associated to an individual the more promising is the individual itself. This is a crucial quantity for the success of the optimization procedure.
- 3. Until a predefined convergence criterion is reached, the following steps are iterated:
 - (a) Some individuals are selected (parents) to be used as a starting point for the generation of new individuals (offsprings).
 - (b) Offsprings are obtained through a suitable mechanism of parents encoding recombination (crossover). In this phase, the chromosomes of the parents, i.e. their encoding, are suitably combined to generate new individuals. A valid crossover should produce individuals whose genetic code is, to some extent, similar to that of the parents. Crossover is usually followed by a random variation, with low probability, of some portions of the derived encoding. Such a process is called mutation and has a crucial importance as it allows to introduce missing genetic code and to keep genetic diversity in the population. The fitness is finally calculated for all newly obtained individuals.
 - (c) Some offsprings live sufficiently long to replace other pre-existing individuals.

The Brain Project: genetic mechanism

from Russo M 2016 Swarm Evo. Comput. **27** 145

The Brain Project: fitness function

Fitness function → is the function to maximize → it suitably contains the prediction error and a term related to the complexity of the model and/or feature costs.

to tune the desired trade-off between accuracy and complexity

$$f_{\text{fit}} = 100.0 * \frac{f_e u(f_e) + \alpha f_n u(f_n)}{1 + \alpha} e^{f_e(1 - u(f_e))} e^{f_n(1 - u(f_n))}$$

$$f_e = \frac{e_{\text{max}} - e}{e_{\text{max}}}$$

related to the accuracy of the model

$$e = 100 \sqrt{\sum_{o=1}^{N_o} \sum_{p=1}^{N_p} \frac{\left(w_pat_p w_out_o(y_{op}^d - y_{op}^c)\right)^2}{N_o N p_{eq}}}$$

$$f_n = \frac{n_{\max} - n}{n_{\max} - 1}$$

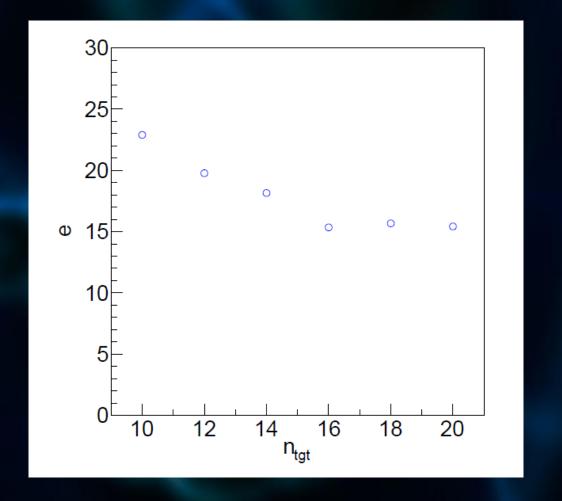

related to the complexity of the model

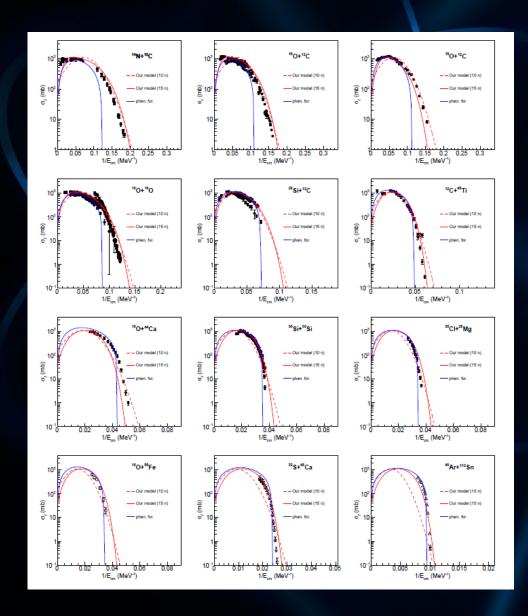

Results

 $f_{fit} = f_{fit} \cdot e^{\frac{n_{tgt}-n}{n_{tgt}}} \rightarrow$ required to reach a predefined, target, number of nodes. Brain Project usually tries to optimize the error with a given number of nodes \rightarrow interesting to more easily tune the complexity of the desired model.

$$\sigma_{fus}^{(n_{tgt}=10)}(E_{cm}) = 1103 \cdot \exp\left[-\left(1.387 - 0.468 \cdot \frac{Z_2 \cdot Z_1}{E_{cm}}\right)^2\right]$$

$$\sigma_{fus}^{(n_{tgt}=15)}(E_{cm}) = 1116 \cdot \exp\left[-\sinh^2\left(-1.359 + \operatorname{erf}\left(\frac{S_{2n}}{E_{cm}}\right) + 0.061 \cdot \frac{A_1 \cdot A_2}{E_{cm}}\right)\right]$$

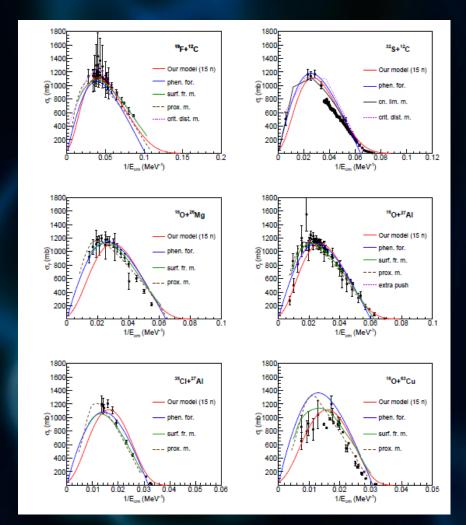

Comparison with other models

Our model slightly overrestimates data in region 0;

Regions I-III > good overall description of data;

The positions of maxima are well reproduced, for lighter systems the maximum is predicted at slightly lower energies;

Nearly-symmetric systems \rightarrow variances in agreement with surface friction model and slightly larger than those obtained with the proximity model.
