

Particle identification with the cluster counting technique in the IDEA drift chamber

Matteo Greco for the cluster counting team

108° Congresso Nazionale della Società Italiana di Fisica

12-16 September 2022, Milano

SOCIETÀ ITALIANA DI FISICA
Italian Physical Society

Outline

- The **cluster counting technique**: a promising method for the particle identification
- The simulation results with **Garfield++** and **Geant4**
- A **test beam** for the validation of the expectations
- Preliminary results: the algorithms to count clusters

The cluster counting technique

- **Particle identification** can be performed using the information of the energy deposit by a track in gas detector → the uncertainties in the total energy deposition represent a limit to the particle separation
- **Cluster counting technique** can improve the particle separation capabilities!!!
- The method consists in singling out, in ever recorded detector signal, the isolated structures related to the arrival on the anode wire of the electrons belonging to a single ionization act (dN_{cl}/dx)

dE/dx

Truncated mean cut (70-80%) reduces the amount of collected information
 $n \approx 100$ and a 2m track at 1 atm give

$$\sigma \approx 4.3\%$$

dN_{cl}/dx

$\delta_{cl} = 12.5/\text{cm}$ for
 $\text{He}/i\text{C}_4\text{H}_{10} = 90/10$ and a 2m track give

$$\sigma \approx 2.0\%$$

This technique will be used for the **IDEA drift chamber** for FCC-ee and CEPC

The cluster counting technique: expected performance

- 80% cluster counting efficiency
- Expected excellent K/π separation over the entire range except $0.85 < p < 1.05$ GeV (blue lines)
- Could recover with timing layer

*Analytic evaluation, prof F.Grancagnolo
To be checked with simulations and experimental data*

Cluster counting for particle identification: simulation results

5

- A simulation of the ionization process in 1 cm long side cell of 90% He and 10% iC_4H_{10} has been performed in **Garfield++** and **Geant4**
- Geant4 software can simulate in detail a full-scale detector
- Three different algorithms have been implemented to simulate in Geant4 the number of clusters and cluster size distributions, using the energy deposit provided by Geant4
- The simulations confirm the predictions: a factor 2 better than dE/dx!

We are assuming a cluster counting efficiency of 100%.

Motivations for a test beam

- Lack of experimental data on cluster density and cluster population for He based gas, particularly in the relativistic rise region
- *Why is particle separation, both with dE/dx and with dN/dx , in Geant4 considerably worse than in Garfield?*
- Despite a higher value of the dN/dx Fermi plateau with respect to dE/dx , *why is this reached at lower values of $\beta\gamma$ with a steeper slope?*

The only way to solve these issues is an experimental measurement! So we planned a test beam in 2 part:

- 1) **November 2021:** demonstrate the ability to count clusters at different gas mixtures and with different drift cell size, different wire material and different wire diameter (muon beam of 165 GeV/c at CERN/H8)
- 2) **July 2022:** measure the number of cluster distribution at different muon momenta (beam of 40, 80, 180 GeV/c at CERN/H8) at different gas mixture, different drift cell size, different wire material and different wire diameter

Experimental setup

- The first part of the test has been done during November 2021 at CERN/H8

- Keep it simple!**
- 11 drift tubes with different cell size and different material wires and diameter wires, to test different configurations

The set up consists of:

- 6 drift tubes 1 cm \times 1 cm \times 30 cm**
 - 1 with 10 μm sense wire, 1 with 15, 2 with 20 μm , 2 with 25 μm
- 3 drift tubes 2 cm \times 2 cm \times 30 cm**
 - 1 with 20 μm sense wire, 1 with 25 μm , 1 with 40 μm
- 2 drift tubes 3 cm \times 3 cm \times 30 cm**
 - 1 with 20 μm sense wire, 1 with 40 μm
- DRS** for data acquisition
- Gas mixing**, control and distribution (only He and iC_4H_{10})
- 2 trigger scintillators

The connection scheme

Trigger scintillator

Two **scintillator** tiles (12 cm x 4 cm), placed upstream and downstream of the drift tubes pack, instrumented with SiPM

The gas system:

- sets the needed gas mixture
- checks the gas pressure at the entrance and at the exit of the tubes
- maintains constant the gas pressure inside the tubes, by using a proportional valve and a pump

Portable gas system

The DAQ system: wave dream board (WDB)

- 16 ch Drs4 REAdout Module
- 16 channels data acquisition board designed and used by the MEG2 experiment at PSI ($\mu \rightarrow e + \gamma$)

Preliminary results: an efficient algorithm to count electrons

The first and second derivative algorithm (DERIV)

Requirements for a good peak candidate in the bin position [ip]:

1. Amplitude constraint:
 - $Amplitude[ip] > 4 * rms$
 - $Amplitude[ip] - Amplitude[ip-1] > rms \ || \ Amplitude[ip+1] - Amplitude[ip-1] > rms$
2. First derivative constraint:
 - $Fderiv[ip] < \sigma_{der1}/2$
 - $Fderiv[ip-1] > \sigma_{der1} \ || \ Fderiv[ip+1] < \sigma_{der1}$
3. Second derivative constraint:
 - $Sderiv[ip] < 0$

0°, nominal HV+20, 90%He-10%iC₄H₁₀
Tube with 1 cm cell size and 20 μm diameter

Expected number of electrons peaks:

$$N_{peak} = \delta_{cluster/cm} \text{ (MIP)} * (\text{drift tube size [cm]}) * 1.3 \text{ (relativistic rise)} * 1.6 \text{ (electron/cluster)} * \frac{1}{\cos(\alpha)}$$

- $\delta_{cluster/cm}$ (MIP) changes from 12 to 18 respectively for 90%He and 80%iC₄H₁₀
- Drift tube size changes from 0.8 to 1.8 respectively for 1 cm and 2 cm cell size tube
- α is the angle of the muon tracks to the detector

The first and second derivative algorithm: results

90%He-10%iC₄H₁₀
60°
nominal HV+20

The mean values are compatible with the ones expected!

The running template algorithm (RTA)

1. Define an electron pulse template based on experimental data
2. Comparing this template with the waveform until a peak is found
3. Subtract the found peak to the signal spectrum
4. Iterating the search
5. Stop when no new peak is found

nominal HV+20

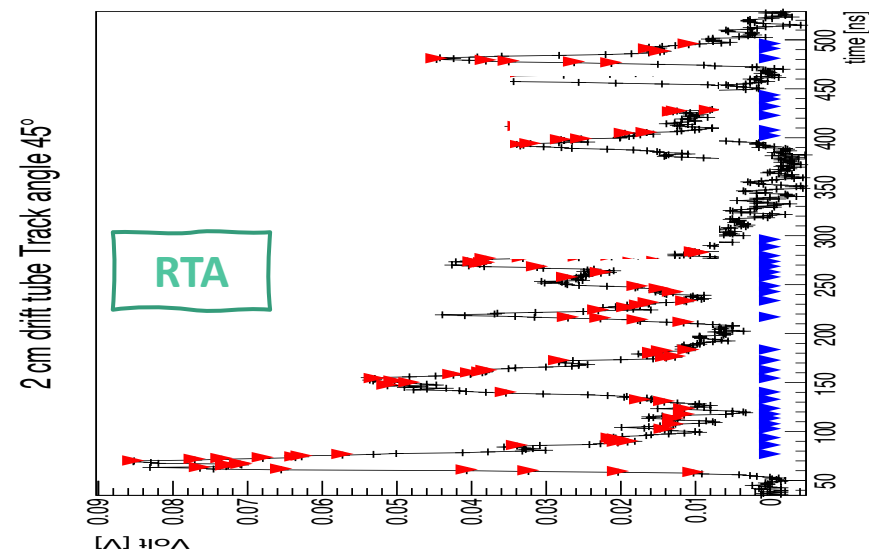

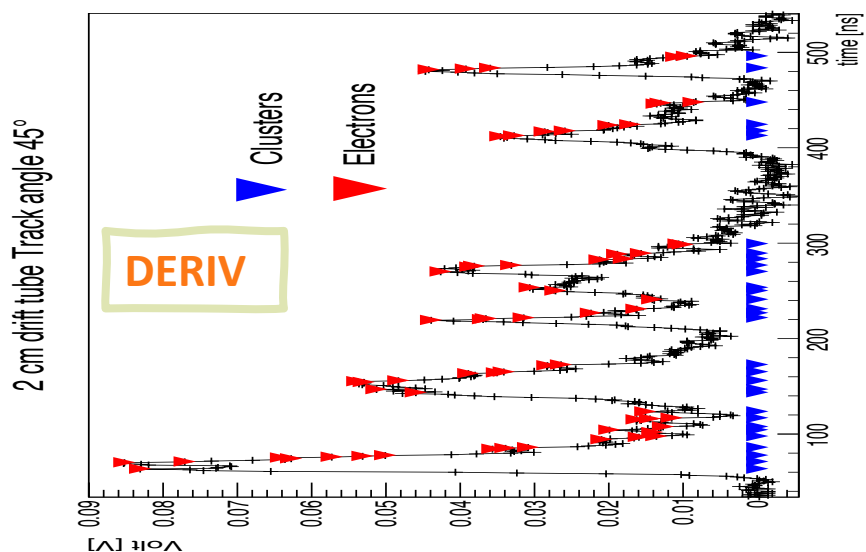

The mean values are compatible with the ones expected!

A single clusterization algorithm

Once found the electron peaks, **clusterization** of the electron peaks into ionization clusters has been implemented:

- 1) Association of electron peaks consisting in consecutive bins (difference in time == 1 bin) electrons to a single electron in order to eliminate fake electrons
- 2) Contiguous electron peaks which are compatible with the electron diffusion time (2.5 ns or 3 bins) must be considered belonging to the same ionization cluster
- 3) Position of the clusters is taken as the position of the last electron in the cluster

Comparison of the two algorithms

POISSONIAN
DISTRIBUTION!

Some news about the ongoing test

- The second part of the test has been done during July 2022 at CERN/H8

- The set up consists of:
 - 12 drift tubes $1\text{ cm} \times 1\text{ cm} \times 30\text{ cm}$
 - 10 with 20 μm sense wire, 2 with 25 μm
 - 8 drift tubes $1.5\text{ cm} \times 1.5\text{ cm} \times 30\text{ cm}$
 - 2 with 15 μm sense wire, 4 with 20 μm , 2 with 25 μm
- We collected data at different percentages of He and isobutane: 90-10, 85-15, 80-20
- For different muon momenta: 40, 80, 180 GeV/c
- At different angles and different HV

Conclusion

- **Cluster counting technique** is a promising method to improve particle separation capabilities
- Analytical and simulations results confirm the expectations, and the test beam plays a key role in this scenario

Next steps:

- Analyzing data from the second part of the test beam
- Optimizing the two cluster counting algorithms and exploiting the possibility of using neural networks or AI and apply them on the new collected data

BACKUP

The IDEA drift chamber

- The **IDEA** drift chamber (DCH) is the tracker of **FCC-ee** and **CEPC**.
- It is designed to provide efficient tracking, high precision momentum measurement and excellent particle identification by exploiting the application of the cluster counting technique.

- **He based gas mixture** (90% He – 10% i-C₄H₁₀)
- **Full stereo configuration** with alternating sign stereo angles ranging from 50 to 250 mrad
- 12 ÷ 14.5 mm wide square cells 5 : 1 field to sense wires ratio
- 56,448 cells
- 14 co-axial super-layers, 8 layers each (112 total) in 24 equal azimuthal (15°) sectors

MAIN GOALS

- **Gas containment – wire support functions separation:**
the total amount of material in radial direction, towards the barrel calorimeter, is of the order of 1.6% X_0 , whereas in the forward and backward directions it is equivalent to about 5.0% X_0 , including the endplates instrumented with front end electronics.
- **Feed-through-less wiring:**
allows to increase chamber granularity and field/sense wire ratio to reduce multiple scattering and total tension on end plates due to wires by using thinner wires
- **Cluster timing:**
allows to reach **spatial resolution < 100 μ m for 8 mm drift cells** in He based gas mixtures (such a technique is going to be implemented in the MEG-II drift chamber under construction)
- **Cluster counting:**
allows to reach **dN_{cl}/dx resolution < 3%** for particle identification (a factor 2 better than dE/dx as measured in a beam test)

Context

- ❑ Offline analysis on November test beam data taken with 165 GeV/c muons beams from **11st November**
- ❑ Dealing with 11 drift tubes having cell sizes of 1-cm, 2-cm and 3-cm:
- **Channels 0,1,2,3** are **Trigger Counters**

- **Channels 4,5,6,7,8,9** are the **6 Drift Tubes of 1 cm cell size** respectively:
 - Channel 4 with a wire diameter of 10 micrometer
 - Channel 5 with a wire diameter of 15 micrometer
 - Channel 6 and 7 with a wire diameter of 20 micrometer
 - Channel 8 and 9 with a wire diameter of 25 micrometer
- **Channels 10,11,12** are the **3 Drift Tubes of 2 cm cell size** respectively:
 - Channel 10 with a wire diameter of 20 micrometer
 - Channel 11 with a wire diameter of 25 micrometer
 - Channel 12 with a wire diameter of 40 micrometer
- **Channels 13,14** are the **2 Drift Tubes of 3 cm cell size** respectively:
 - Channel 13 with a wire diameter of 25 micrometer
 - Channel 14 with a wire diameter of 40 micrometer

Signal acquisition window is out of the signal range

Additional info on DERIV algorithm

First and second derivative have been evaluated in code doing:

NOTE:

```
fderiv[ip] = (Waves_normalized.Y[ip+1]-Waves_normalized[ip-1])/2
```

```
sderiv[ip] = (fderiv[ip+1]-fderiv[ip-1])/2
```

```
sigd1 = rms/sqrt(2)
```

```
sigd2 = rms/2
```

The rms has been computed as:

NOTE: r.m.s. has been defined over the first 30 bins as the $r.m.s. = \sqrt{\frac{\sum_{i=0}^{30} (Wave_normalized[channel].Y - bsl_n)^2}{30}}$

dE/dx and dN/dx resolution comparison

$$\frac{\sigma_{dE/dx}}{(dE/dx)} = 0.41 \cdot n^{-0.43} \cdot (L_{track} [m] \cdot P [atm])^{-0.32}$$

from Walenta parameterization (1980)

$$\frac{\sigma_{dN_{cl}/dx}}{(dN_{cl}/dx)} = (\delta_{cl} \cdot L_{track})^{-1/2}$$

from Poisson distribution

$$\begin{aligned} L_{track} &= 0.6 \text{ m} \\ P &= 1 \text{ atm} \\ n &= 64 \end{aligned}$$

$$\begin{aligned} L_{track} &= 0.6 \text{ m} \\ \delta_{cl} &= 12.5/\text{cm} \end{aligned}$$

$$\frac{\sigma_{dE/dx}}{(dE/dx)} = 8.1\%$$

$$\frac{\sigma_{dN_{cl}/dx}}{(dN_{cl}/dx)} = 3.6\%$$

The DAQ system: WDB wave dream board

- 16 ch Drs4 REAdout Module (Domino Sampling Rate)
- 16 channels data acquisition board designed and used by the MEG2 experiment at PSI ($\mu \rightarrow e + \gamma$)

- **Analog switched capacitor array:** analog memory with a depth of 1024 sampling cells, perform a “sliding window” sampling.
 - **500MSPS \leftrightarrow 5GSPS** sampling speed with **11.5 bit** signal-noise ratio
 - 8 analog channels + 1 clock-dedicated channel for sub 50ps time alignment
 - Pile-up rejection $O(\sim 10 \text{ ns})$
 - Time measurement $O(10 \text{ ps})$
 - Charge measurement $O(0.1\%)$
-
- The recent version, DRS4, is capable of digitizing 9 differential input channels at sampling rates of up to 6 Giga-samples per second(GSPS) with an analogue bandwidth of 950MHz(3 dB).
 - The channel depth can be configured between 1024 and 8192 cells, and the signal-to-noise ratio allows a resolution equivalent to more than 11 bits.
 - The high bandwidth, low power consumption and short readout time make this chip attractive for many experiments, replacing traditional ADCs and TDCs
